

ECOREGION Bay of Biscay and Atlantic Iberian waters
STOCK Sardine in Divisions VIIIc and IXa

Advice for 2015

ICES advises on the basis of precautionary considerations, and taking into account the current low biomass that catches in 2015 should be no more than 16 000 tonnes. Discards are considered to be negligible and all catches are assumed to be landed.

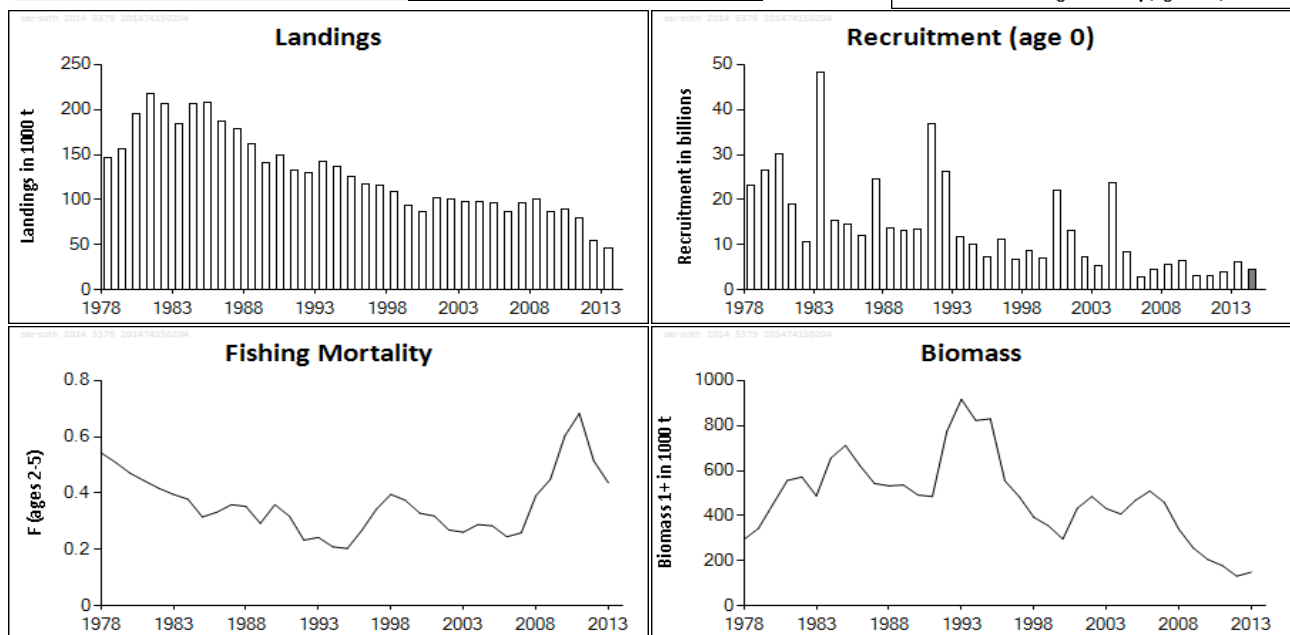

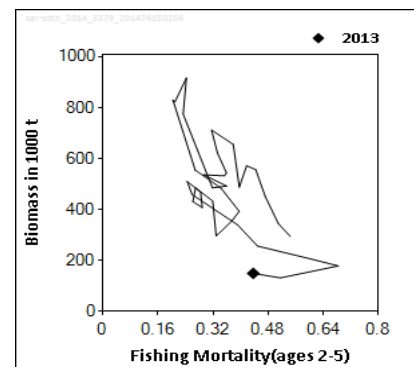

Figure 7.3.19.1 Sardine in Divisions VIIIc and IXa. Summary of stock assessment (weights in thousand tonnes, biomass expressed in weight-at-age 1 and older fish; Biomass 1+). Top right: Biomass 1+ and F over the years. Assumed recruitment values are shaded.

The biomass of age 1 and older fish has decreased since 2006 and is currently around the historic low. Recruitment has been below the long-term average since 2005. Fishing mortality since 2009 has been above the average of the last two decades prior to 2009.

Management plans

ICES has evaluated a proposed management plan developed by Portugal and Spain (ICES, 2013a, Annex 7.3.19). ICES concluded that the proposed management plan is provisionally precautionary.

Biology

Sardine is prey for a range of fish and marine mammal species. Sardine is an omnivorous predator able to feed on both phytoplankton and zooplankton. In addition, sardines have been found to ingest their own eggs (and probably those of other species) and this cannibalism may act as a density control mechanism.

Environmental influence on the stock

As one of the most abundant pelagic forage fish species in Iberian waters, sardine may exert bottom-up control of their predators or top-down control of their prey, or they may control both prey and predators.

The fisheries

Most catch is taken by purse-seiners. Sardine catches are highest in the second half of the year and catches are traditionally concentrated mainly in western part of Portugal, Galicia and Cantabrian Sea. Catches in the Gulf of Cadiz and Algarve areas have increased since 2011. In Spain, vessels target anchovy, mackerel, sardine, and horse mackerel; in summer, part of the fleet switches to tuna fishing. In Portugal, sardine is the main target species, but chub mackerel, horse mackerel, and anchovy are also landed. Most catches are taken off the northern coast. Discards are uncertain but are assumed to be negligible. Slipping estimates are available for the Portuguese fleet, but with a limited coverage in time and extent.

Catch distribution Total catch (2013) = 46 kt, where 46 kt were official landings (99% purse-seine and 1% other gear types). Discards are assumed to be negligible.

Effects of the fisheries on the ecosystem

Purse-seines have a low bycatch of non-target species: when targeting sardine, the catches are mostly monospecific. Observer data and interview surveys of fishers also indicate a low impact on megafauna such as cetaceans, seabirds, and turtles. Because purse-seiners operate in open waters, there is little impact on the seabed. The overall effect of the sardine fishery on the pelagic ecosystem of the Atlantic Iberian waters has not been evaluated. The most likely impacts will take place in alterations of prey-predator relationships via modification of sardine abundance, size structure, and behaviour.

Quality considerations

The main uncertainties in the assessment relate to the discrepant signals about the stock trends provided by the daily egg production method (DEPM) and acoustic surveys. Uncertainty continues regarding the extent of sardine movement across the northern stock boundary, on the comparability of Portuguese and Spanish acoustic surveys, on survey and fishery selection patterns, and on the weighting of the different data sources in the assessment.

Figure 7.3.19.2 Sardine in Divisions VIIIc and IXa. Historical assessment results (final-year recruitment and biomass estimates included). The stock was benchmarked in 2012.

Scientific basis

Stock Data Category	1 (ICES, 2014a)
Assessment type	Age-based analytical assessment (SS3).
Input data	Commercial catches (international landings, ages and length frequencies from catch sampling), survey indices (PELAGO&PELACUS-Q2, PT-DEPM&SP-DEPM). Annual maturity data from DEPM survey, and natural mortalities from Gislason formula.
Discards and bycatch	Not included and are considered negligible.
Indicators	None
Other information	Benchmarked in February 2012 (WKPELA ; ICES, 2012).
Working group	Working Group on Anchovy and Sardine (WGHANSA)

Management plan

ICES has evaluated a management plan as requested by the EC (ICES, 2013a). The management plan description can be found in Annex 7.3.19. ICES concluded that the plan is provisionally precautionary, causing low probabilities of unsustainable fishing mortality, when the biomass used for comparison in the harvest control rule is the B₁₊ in the beginning of the intermediate year.

Following the proposed EC management plan implies that the TAC is set by the formula $0.36 \times (B_{1+}(2014) - \text{lower trigger level}) = (0.36 \times (188 - 135))$ because the biomass is currently between the two trigger points in the harvest rule, which implies catches of no more than 19 095 t in 2015. Discards are considered to be negligible and all catches are assumed to be landed.

Precautionary considerations

The stock biomass is at a historically low level and fishing mortality peaked in 2010–2011. It has decreased since then but it is still above the long-term average. F should be brought back to where it was before the start of this increase, i.e. the 2002–2007 average (0.27). However, taking into account the low biomass, below previous B_{loss} and the below-average recruitment, ICES considers fishing mortality F should be reduced further. This reduction is based on the ratio between the current biomass ($B_{1+(2014)} = 188\ 000$ t) and the average biomass in the period before high fishing mortality occurred (average $B_{1+(2002-2007)} = 406\ 000$ t, ratio of 41%) to $F = 0.11$. This results in catches of no more than 16 000 t. Discards are considered negligible and all catches are assumed to be landed.

Additional considerations

Management plan evaluations

ICES has evaluated a proposed management plan developed by Portugal and Spain (ICES, 2013a). Given the available data, ICES was unable to define reference points to use for the evaluation. ICES concludes the plan is provisionally precautionary, because it gives low probabilities of exceeding F_{loss} or driving B₁₊ below B_{loss} and a high probability of rapid recovery when B₁₊ declines to below trigger values. The proposed plan implies a relatively modest exploitation

rate with mean $F = 0.22$, which is 70% of the natural mortality. As an F slightly lower than the natural mortality is a potential proxy for F_{MSY} (Deriso, 1982), the plan results in exploitation in the lower range of candidate F_{MSY} values.

Further exploration of sardine stock dynamics is required; for example it may be possible to draw inferences from studies of other sardine stock dynamics at low biomass. This will provide a better informed basis for determining precautionary criteria which may improve the evaluation of the current proposed plan. Additionally, alternative settings (lower target catch, higher trigger points) and catch stabilizers could be tested to improve the performance of the plan and make it more precautionary.

Regulations and their effects

There is no international TAC. Almost all catches are taken by purse-seiners in a directed human consumption fishery. Until 2014, the fisheries are managed by Portugal and Spain through minimum landing size, maximum daily catch, days fishing limitations, and closed areas.

Since 2010, annual catch limits are set for the Portuguese fishery by the Portuguese authorities. In 2013, the catch limit was 36 000 t, following the multiannual management plan.

In Spain, management measures include a maximum allowable catch of 7000 kg per fishing day and a 5-fishing-days week limitation since 1997.

In both countries, fishing for sardine was banned for 45 days during the first quarter of the year, with different regional periods.

Biology

Sardine is distributed in the Iberian region, to the north in Subareas VII and VIII and in the North Sea, and to the south on the Moroccan shelf. The information presented here assumes that sardine in Divisions VIIIc and IXa is a unit stock, based on biological characteristics. However, some movement of fish between Divisions VIIIb and VIIIc is known to occur. The effect of this movement is uncertain but is presently considered to have little influence on the estimation of the stock in the assessed area (Divisions VIIIc and IXa).

The environment

Sardine recruitment is considered to be influenced at both the local and the global scale by environmental variables that may reduce the transportation of eggs and larvae offshore which are critical to ensuring egg and larval survival. Indirect effects, e.g. on growth and condition through variations in food supply or water temperature have been given less attention. Results from such studies show that environmental effects, although present, are often weak and in some cases findings have been contradictory. For example, upwelling intensity has been found to affect recruitment both positively and negatively.

The Iberian sardine is considered a forage fish, i.e. a fish that provides food for predatory fish as well as marine mammals and birds. Sardine is one of the most abundant small pelagic species in western Iberian waters and has been found to be important in the diet of several species of fish and marine mammals. Forage fish such as sardine may exert bottom-up control of their predators or top-down control on their zooplanktonic prey, or they may control both prey and predators (wasp-waist control).

Uncertainties in assessment and forecast

The assessment shows a retrospective pattern overestimating SSB and underestimating F is observed in the last 3 years.

The DEPM and the acoustic surveys show discrepant signals in the stock trajectory. The assessment tends to accommodate the signals from the two surveys by providing a broad average perspective but follows the acoustic survey in the years when the DEPM is not available.

Some unresolved technical issues in the software code prevented the inclusion of confidence interval in fishing mortality. Hence confidence intervals are not shown.

Comparison of the basis of previous assessment and advice

The basis for the assessment has not changed from last year, but the forecast has been amended to account for changes in F in recent years (the intermediate year F was scaled to 2013). The basis for the advice is the same as last year: precautionary considerations.

Annex 7.3.19 Proposed management plan

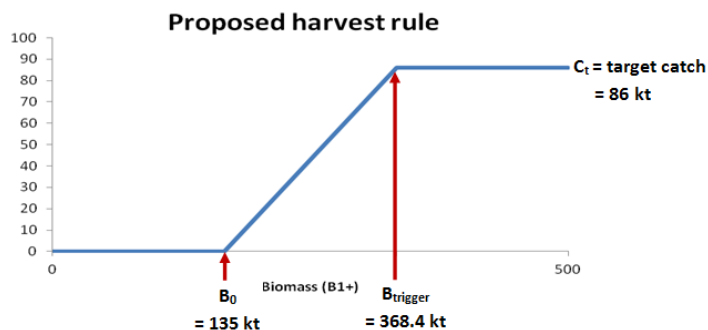

In the document referred to in the plan (*Plan de gestion sardina*), the harvest rule is stated as:

$$\begin{aligned} B_{1+} > B_{\text{trigger}} &\rightarrow C_{\text{MAX}} = C_t \text{ kt} \\ B_0 < B_{1+} < B_{\text{trigger}} &\rightarrow C_{\text{MAX}} = d(B_{1+} - B_0) \text{ kt} \\ B_{1+} < B_0 &\rightarrow C_{\text{MAX}} = 0 \end{aligned}$$

where

- B_{1+} = the biomass of the ages 1 and older, in kt ¹⁾
- C_{MAX} = maximum catch in kt
- B_{trigger} = 368.4 kt (1.2 B_{lim})
- d = 0.36
- B_0 = 135 kt
- C_t = target catch = 86 kt.

The harvest rule is illustrated in the figure below:

The harvest rule sets a TAC directly according to an estimate of the biomass of fish aged 1 and older (B_{1+}). The TAC is fixed at C_t when B_{1+} is above B_{trigger} , and reduced if it is below.

ICES has not defined a B_{lim} for this stock, but for the purposes of the formulation of this plan the value is taken as B_{loss} in 2000 according to the 2012 assessment.

¹ For the purpose of this evaluation the B_{1+} in the beginning of the intermediate year is used.
